Note : Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

The present invention relates to a device and a method for detecting the presence of an article, more particularly, it relates to an article detection device used with a bar code reader.

Recently, bar code readers are widely utilized for management of goods in a POS (Point Of Sales) system. In general, there are two types of bar code readers, i.e., an installed type and a handheld type. The former is large and installed in a counter of large store. This type has a plurality of scanning beams (laser beams) to be irradiated onto a bar code symbol so that it is possible to provide highly precise detection of the bar code symbol regardless of a direction of entry of the article into an scanning area of the laser beam. Further, in general, this type has an article detection device for detecting the entry of the article into the scanning area of the laser beam before the laser beam is turned on. Since the laser beam is turned on after detection of the article, it is possible to extend the life of a laser beam source.

In general use, the operator of a bar code reader sits behind the article. However, the light reflected from the operator should not be detected as an article by the article detection device. Further, random external light (ambient light), for example, fluorescent lamps and sunlight, exists around the article, and the light reflected from the operator and the ambient light have an undesirable influence on the detection of the bar code symbol.

Accordingly, it is necessary to eliminate the influence of this reflected light so as to increase the reliability of detection of articles.

It is therefore desirable to provide an article detection device (i.e. device for detecting the presence of an article), and a method for detecting the presence of an article, in which the presence of an article can be reliably detected regardless of the influence of ambient light reflected from various sources.

US-A-4 694 182 discloses a hand held bar code reader using a modulated laser diode as a light source. By modulating the diode, and timing the reading detector accordingly, the effects of strong ambient light can be subtracted out.

EP-A-0 323 848 discloses a device and a method according to the preambles of accompanying claims 1 and 12. Detection of the presence of an article is achieved using an article detection circuit which integrates and smooths a received light signal, and which generates an article detection signal to activate a main light source and a bar code reader.

GB-A-2 114 792 discloses an apparatus for recognising optical code markings which employs photoreceivers for detecting the presence or absence of an article.

In accordance with the present invention, there is provided a device for detecting the presence of an ar-

ticle, including: a light emission unit for emitting detection light onto an article; and a light reception unit for receiving light reflected from the article; and characterised by : an analog-to-digital converter for converting the reflected light to a digital signal; a first register for storing the digital signal after being sampled using a first sampling signal having a first period; a second register for storing the digital signal after being sampled using a second sampling signal having a second period shorter than the first period; and a control unit for generating the first and second sampling signals to be sent to the first and second registers, reading the digital signal stored in the first and second registers, calculating a difference between the digital signals in the first register and second register, comparing an absolute value of the difference with a predetermined threshold value, and detecting the presence of an article when the absolute value is larger than a threshold value.

In one embodiment, the article detection device further comprises: an AC-amplifier connected to the light reception unit for amplifying the reflected light; a sample/hold unit connected between the AC-amplifier and the A/D converter for sampling and holding an alternating signal amplified by the AC-amplifier; and a modulation unit for generating a pulse modulation signal to be sent to a drive unit which pulse-drives the light emission unit; wherein the control unit further generates control signals to be sent to the modulation unit, the sample/hold unit, and the A/D converter to control the operation of these units.

In another embodiment, the control unit comprises a storage unit for storing a number of sampling times and storing a threshold value comprised of a first and second threshold values.

In still another embodiment, the sample/hold unit comprises a maximum sample/hold circuit for sampling and holding a maximum value of the alternating signal, a minimum sample/hold circuit for sampling and holding a minimum value of the alternating signal, and a differential amplifier for amplifying a difference between the outputs of the maximum sample/hold circuit and the minimum sample/hold circuit.

In still another embodiment, the sample/hold unit further comprises a first delay unit for delaying a first sampling signal, and a second delay unit for delaying a second sampling signal, the first sampling signal is input to the maximum sample/hold circuit, and the second sampling signal is input to the minimum sample/hold circuit.

In still another embodiment, an article detection device further comprises: a difference calculation unit having a differential amplifier for calculating a difference between a level of background reflected light and a lower limitation level, the background reflected light being detected from the background of the article, and the lower limitation level being adjusted in accordance with the intensity of the background

reflected light in an adjusting mode; and detection means for detecting a change in amount of light based on the resultant data of the above calculation to eliminate the influence of the ambient light.

In still another embodiment, the intensity of the background reflected light is determined by a reference reflection face having a predetermined reflection rate.

In still another embodiment, the article detection device comprises a sample/hold circuit for sampling and holding the output of the differential amplifier, an adjusting circuit for adjusting the lower limitation level, a first A/D converter for converting the output of the differential amplifier to a digital value, a second A/D converter for converting the output of the sample/hold circuit to a digital value, and a third A/D converter for converting the output of the adjusting circuit to a digital value.

In still another embodiment, the article detection device further comprises an adjusting unit for adjusting the gain of an amplifier connected to the light reception element, and a reference voltage generation unit for generating first and second reference voltages to be supplied to the amplifier, wherein the adjustment of the gain of the amplifier is performed in such a way that when ambient light does not exceed a predetermined threshold level, the first reference voltage is selected and the gain is adjusted to a high level, and when the ambient light does exceed a predetermined threshold level, the second reference voltage is selected and the gain is adjusted to a low level.

In still another embodiment, the adjusting unit comprises a plurality of analog switches, a first analog switch being used for switching the gain between the high level and the low level, a second analog switch is used for switching between detection of ambient light and the light reflected from an article, and a third analog switch is used for switching the reference voltage between the first and the second reference voltages. The switching of these analog switches is performed by selection signals generated by the control unit.

In still another embodiment, the control unit comprises a microprocessor.

As another aspect of the present invention, a method for detecting the presence of an article comprises the steps of: emitting detection light to be irradiated onto an article; and receiving light reflected from the article; and is characterised by the further steps of: converting the light reflected to a digital signal; storing the digital signal in a first register after being sampled using a first sampling signal generated by the control unit and having a first period; and storing the digital signal in a second register after being sampled using a second sampling signal generated by the control unit and having a second period shorter than the first period. In the control unit, the steps of: reading the digital signal stored in the first and second

registers; calculating a difference between the digital signals in the first register and second register; comparing an absolute value of the difference with a predetermined threshold value; and detecting the presence of an article when the absolute value is larger than the threshold value, are carried out.

In another embodiment, the detecting step further comprises the step of: defining first and second threshold values included in the threshold value, detecting the presence of an article when the absolute value is larger than the first threshold value, and detecting that an article is not present when the absolute value is smaller than the second threshold value.

In still another embodiment, the detecting step further comprises the steps of: checking whether or not a number of sampling times reaches a predetermined number of sampling times when the absolute value is smaller than the first threshold value, and returning to previous sampling steps.

In still another embodiment, the detecting step further comprises the steps of: checking whether or not a number of sampling times reaches a predetermined number of sampling times when the absolute value is larger than the second threshold value, returning to a previous sampling step of the second sampling signal when the number of sampling times does not reach a predetermined number of times, and detecting that an article is not present when the absolute value is smaller than the second threshold value or when the number of sampling times reaches a predetermined number of times.

In still another embodiment, a method for detecting an article further comprises the steps of: setting a first and second reference voltage, detecting ambient light before detecting the presence of an article; comparing the ambient light with a predetermined threshold value; and adjusting the gain of an amplifier in accordance with the ambient light so as to switch between first and second reference voltages.

In still another embodiment, a method for detecting an article further comprises the steps of: calculating a difference between a level of background reflected light and a lower limitation level in an adjusting mode; and detecting a change in amount of light based on resultant data of the above calculation to eliminate the influence of the ambient light.

Before describing the preferred embodiments, an explanation will be given of the conventional art.

Figure 1A is a view for explaining an article detection area and a bar code read area of a bar code reader. As shown in the drawing, the bar code reader is basically constituted by an article detection unit and a bar code read unit. An article detection light is emitted from the article detection unit in the range of the article detection area (slanted area) to detect the presence of an article. The laser beam is emitted from the bar code read unit to read the bar code symbol of the article. The article detection area RA overlaps with the bar code read area SA to realize precise detection of the article. When the article detection unit detects an article in the article detection area RA, the laser beam source is turned on and the laser beam is emitted onto the bar code symbol.

Figure 1B is a basic circuit of the article detection unit shown in Fig. 1A. The detection light DL is emitted from the light emission element 1, and the light reflected from the article RL is received by the light reception element 2 and amplified by the amplifier 6a. In the comparator 6b, the amplified signal is compared with the threshold level V_{th} and the article detection signal DS is output when the amplified signal is larger than the threshold level V_{th} .

Figure 1C is a view for explaining an article detection signal DS from the comparator 6b. As shown in the drawing, when the reflected light level RL exceeds the threshold level V_{th} , the article detection signal DS is emitted from the comparator 6b. That is, although various detection lights are reflected from the article and the background, the light level reflected from the article itself is larger than the threshold

level V_{th} .

In this case, the reflection light level RL fluctuates in accordance with a color in the background. For example, when the operator wears white, the reflected light level RL becomes large. Accordingly, when the reflected light from the background accidentally exceeds the threshold level V_{th} as shown by dotted line RL', the undesired reflected light RL' is detected as the article detection signal.

Figure 2A is a basic block diagram of an article detection device according to a first embodiment of the present invention. In Fig. 2A, the same reference numbers as used in Fig. 1A are attached to the same components in this drawing. Reference number 3 denotes an analog-to-digital converter, 4a and 4b registers, and 5a control unit. Further, M1 denotes a first sampling signal, and M2 denotes a second sampling signal. The signal Sd from the A/D converter is input in parallel to the first register 4a and the second register 4b.

The first register 4a stores the signal Sd after being sampled using the sampling signal M1 having a first period T1, and the second register 4b stores the signal Sd after being sampled using the sampling signal M2 having a second period T2. The period of the sampling signal M2 is shorter than that of the sampling signal M1. The control unit 5 generates the first and second sampling signals M1 and M2 which are applied to the first and second registers 4a and 4b. Further, the control unit 5 calculates the difference between the data stored in the first and second registers 4a and 4b, compares the absolute value of that difference with the threshold value, and detects the article when the absolute value exceeds the threshold value.

Figure 2B is a signal timing chart of the device shown in Fig. 2A. As shown in the drawing, the period T2 of the sampling signal M2 is considerably shorter than that of the sampling signal M1. For example, the period T1 may be set to 5 sec, and the period T2 set to 2 msec. The light reflected from the background is detected during the period T1 of the sampling signal M1, and the light reflected from the article is detected during the period T2 of the sampling signal M2. Accordingly, as explained in detail hereinafter, the article is detected when the absolute value of the difference between the reflection level of the background and that of the article exceeds the predetermined threshold value.

Figure 3 is a detailed block diagram of the article detection device shown in Fig. 2A. Reference number 7 denotes a modulation unit, 8 a drive unit, 9 an alternating (AC) amplifier, and 10 a sample/hold unit. Further, CTLa to CTLc denote control signals generated from the control unit 5 to control the operation of these units 3, 7, and 10, C1 and C2 denote the number of sampling times, V_{th1} denotes a threshold level when an article is present, and V_{th2} denotes a thresh-

old level when an article is not present. These values of C1, C2 and Vth1, Vth2 are store in a storage means of the control unit 5.

The modulation unit 7 generates a pulse modulation signal Sm to the drive unit 8 in response to the control signal CTLa. The drive unit 8 drives the light emission element 1 in response to the pulse modulation signal Sm so that a pulsed detection light DL is emitted from the element 1.

The reflection light RL from the article is received by the light reception element 2 and alternatively amplified by the AC-amplifier 9. The amplified signal Sa is input to the sample/hold unit 10 for sampling and holding the amplified signal. The control unit 5 is constituted by, for example, a microprocessor (CPU).

Since the detection light DL is emitted in pulses, it is possible to extend the life of the element 1, and to reduce power consumption.

Figure 4 is a flowchart for explaining the processing of signals in the circuit shown in Fig. 3.

① First, the CPU initializes each unit.

② Next, the CPU resets the number of times C1 of the sampling signal M1 to "0". Further, the digital signal Sd is input to the first register 4a in response to the sampling period of the sampling signal M1.

③ The CPU sends the sampling signal M2 to the second register 4b. The digital signal Sd is input to the second register 4b in response to the period of the sampling signal M2.

Next, the CPU reads the sampling data D1 using the sampling signal M1 from the first register 4a and the sampling data D2 using the sampling signal M2 from the second register 4b. Further, the CPU calculates the difference between the sampling data D1 and the sampling data D2 (i.e., $D1 - D2$), obtains the absolute value $|D1 - D2|$ of the difference, and compares the absolute value $|D1 - D2|$ with the threshold value Vth1.

④ In step ③, when the absolute value $|D1 - D2|$ is not larger than the threshold value Vth1 ("NO"), the CPU judges that an article is not detected, and updates the number of times C1 of the sampling to $C1 + 1$. The CPU then checks whether or not the number of times C1 has reached the predetermined number of times X1. When the number of times C1 reaches X1, i.e., $C1 = X1$ ("YES"), the process returns to the step ② to start from $C1 = 0$. If the number of times C1 has not reached X1, i.e., $C1 \neq X1$ ("NO"), the process returns to the step ③ to read the data D1.

⑤ In step ③, when the absolute value $|D1 - D2|$ is larger than the threshold value Vth1 ("YES"), the CPU judges that an article is present, and performs the processing for the case in which an article is present. That is, the CPU starts the bar code read unit to irradiate the laser beam onto the

bar code.

⑥ The CPU then again reads the data D2 in the period T2 from the register 4b to ensure precise detection of the article. That is, the CPU again calculates the difference between the sampling data D1 and the sampling data D2 (i.e., $D1 - D2$), obtains the absolute value $|D1 - D2|$, and compares the absolute value $|D1 - D2|$ with the threshold value Vth2.

⑦ In step ⑥, when the absolute value $|D1 - D2|$ is not smaller than the threshold value Vth2 ("NO"), the CPU judges that an article may be present in the detection area, and updates the number of times C2 of the sampling to $C2 + 1$. The CPU then checks whether or not the number of times C2 has reached the predetermined number of times X2. If the number of times C2 has not reached X2, i.e., $C2 \neq X2$ ("NO"), the process returns to the step ⑥ to repeat from the step ⑥. When the number of times C2 reaches X2, i.e., $C2 = X2$ ("YES"), the process proceeds to the step ⑧. In this case, the CPU judges that the article is present, but it has not moved into detection area.

⑧ In step ⑥, when the absolute value $|D1 - D2|$ is smaller than the threshold value Vth2 ("YES"), and when the article is present, but it has not moved into the detection area, the CPU performs the processing for the case in which no article is present in the detection area. That is, the CPU resets the number of times C2 of the sampling to "0", and the process returns to the step ②.

Figures 5A to 5F are signal timing charts of the present invention. In Fig. 5A, the ordinate denotes the intensity of light reflected from the background or an article. The article detection unit detects the reflected light RL1 of the background changing from intensity "2" to intensity "4", and also detects the reflected light RL2 of the article changing from intensity "0" to intensity "4". In this case, the change of the reflection light intensity RL2 of the article is quite large because the article is present in front of the article detection unit for every reading operation.

In Figs. 5B and 5C, the period T1 of the sampling signal M1 is very large compared with the period T2 of the sampling signal M2. As explained above, for example, the period T1 is set to 5 sec, and the period T2 is set to 2 msec. In this case, the period T1 is used for sampling the light reflected from the background, and period T2 is used for sampling the light reflected from the article.

In Figs. 5D and 5E, the data D1 denotes the sampling data stored in the register (R1) 4a based on the period T1, and the data D2 denotes the sampling data stored in the register (R2) 4a based on the period T2.

In Fig. 5F, this chart shows the absolute value of the difference between the data D1 and the data D2. That is, the CPU subtracts the data D2 from the data

D1, and obtains absolute value $|D1 - D2|$. Further, the absolute value $|D1 - D2|$ is compared with the predetermined threshold value.

Accordingly, in the present invention, since two different sampling periods T1 and T2 are used for detecting the background and the article and the absolute value $|D1 - D2|$ is compared with the threshold values Vth1 and Vth2, it is possible to eliminate the influence of the light reflected from the background so that it is possible to perform precise detection of the article. Further, as shown in step ⑧, when the CPU judges that an article exists but does not move, since the CPU performs the processing for the base in which no article is present, it is possible to reduce the necessary time for detecting the article.

The article detection unit according to the present invention can of course be applied to another type of system instead of a bar code reader.

Figure 6A is a basic block diagram of the article detection unit according to a second embodiment of the present invention. This embodiment is advantageous for detection of an article in a case where the background moves. In Fig. 6A, reference number 11 denotes a difference calculation unit, and 12 denotes a detection unit for detecting a change in amount of light. These units are provided in the article detection unit. Briefly, the difference calculation unit 11 subtracts a lower limitation level LL from the background reflected light RS and obtains a difference value D thereof. The detection unit 12 detects the change in the amount of light based on the difference light value D as explained in detail hereinafter.

Figure 6B is a view for explaining the principle of the second embodiment. In Fig. 6B, the ordinate denotes the output level of the light reception element, and the abscissa denotes the distance from the article to the article detection unit. The line O-P-Q (dotted line) denotes the relationship between the output and the distance. As is obvious from the drawing, the output level linearly reduces in proportion to the distance. In this case, the lower limitation level is defined by movement of the background as explained below.

When the output level (i.e., reflected light level) is limited by the lower limitation level LL, the output light lower than the limitation level LL is not detected by the article detection unit. Accordingly, the light to be detected by the article detection unit can be expressed by the line O'-P'-Q' (solid line). In other words, it is possible to consider that the distance from the article to the article detection unit is close to a distance L1. Therefore, it is possible to eliminate a light reflected from the background which moves in the detection area.

Figure 7 is a detailed block diagram of the second embodiment shown in Fig. 6A, and Figure 8 is waveforms of each block shown in Fig. 7.

In Fig. 7, reference number 2a denotes an optical-to-electrical (O/E) converter, and 13 a high-pass

(H/P) filter. 17a denotes a maximum sample/hold (S/H) circuit, 17b a minimum sample/hold circuit, 18 and 20a differential amplifiers (DIF-AMP), 19 a sample/hold circuit, and 22a and 22b delay circuits. The registers 21a and 21b correspond to the registers 4a and 4b in Fig. 3, and the CPU 24 corresponds to the control unit 5 in Fig. 3. Further, reference number 25 denotes an adjusting circuit for the lower limitation level, and 26 denotes an A/D converter.

The signal A amplified by the AC amplifier 14 is input to the maximum and minimum sample/hold circuits 17a and 17b. The signal A is shown by the solid line in Fig. 8, and the signals B and C are shown by the dotted lines in Fig. 8. The maximum sampling/holding operation is performed in response to a sample/hold signal CTL1-DLY generated from the delay circuit 22a, and the minimum sampling/holding operation is performed in response to a sample/hold signal CTL2-DLY generated from the delay circuit 22b. Signals CTL1 and CTL2 are the sample/hold signals before being delayed by the delay circuits. The signals CTL1 and CTL2 are generated from the CPU 24.

In this case, each pulse width of the CTL1-DLY and the CTL2-DLY is narrower than that of the CTL1 and CTL2. This is because it is necessary to use the flat portion of the signal A. That is, the signal CTL1-DLY synchronizes with the signal A, and is used for sampling the maximum range (flat portion) of the reflection light of the signal A. Similarly, the signal CTL2-DLY synchronizes with the signal A, and is used for sampling the minimum range (flat portion) of the reflection light of the signal A.

The differential amplifier 18 amplifies the difference value between the signals B and C and obtains the signal D shown in Fig. 8. The sample/hold circuit 19 outputs the signal E in response to the sample/hold signal CTL3 from the CPU 24. The differential amplifier 20a calculates the difference between the signal E and the lower limitation level LL, and the difference value is converted to a digital signal by the A/D converter 20.

The register 21a stores the digital signal in response to the sampling signal CTL4 from the CPU, and the register 21b stores the digital signal in response to the sampling signal CTL5 from the CPU. The adjusting circuit 25 is constituted by a resistor r1 and a variable resistor r2, and is provided for adjusting the lower limitation level by means of the variable resistor r2.

The adjustment of the lower limitation level is explained in detail hereinafter. The lower limitation level LL is adjusted before the detection of the article is started (i.e., adjustment mode). The signal E is converted to the digital signal S1 by the A/D converter 23 and the digital signal S1 is input to the CPU as the adjustment mode. In the adjustment mode, the detection light DL is emitted in pulses from the light emission element 1. Next, a reference reflection face (not

shown) is provided instead of the article at the distance L_1 (for example, $L_1 = 40$ cm) from the article detection unit. The reference reflection face has a reference reflection rate (for example, 30%). The detection light DL is reflected by the reference reflection face, and received by the light reception element 2. The received signal is transferred to the sample/hold circuit 19 through the units 13, 14, 17a, 17b, and 18.

The digital signal S1 from the A/D converter 23 is displayed on a display apparatus (not shown). The lower limitation level LL is adjusted by the variable resistor r1 in reference to the display. Further, the lower limitation level LL is converted to a digital signal S2 by the A/D converter 26 and displayed on the display apparatus. Accordingly, the operator adjusts the variable resistor r1 (signal S2) so as to coincide with the digital signal S1 of the A/D converter 23. The adjusted lower limitation level LL indicates the reflected light level from the background.

Figure 9 is a detailed block diagram of a third embodiment of the present invention. The same reference numbers as used in Fig. 7 are attached to the same components in this drawing. This embodiment is provided as a countermeasure for ambient light, for example, fluorescent light and sunlight existing in the article detection area. When this ambient light is strong, the light reflected from the article is disturbed so that it is not possible to precisely detect the article.

In Fig. 9, AS1 to AS5 denote analog switches, and 27 denotes a reference voltage generation circuit. Further, Vref1 and Vref2 denote first and second reference voltages, and IV an inverter. The analog switch AS1 is provided for adjusting the gain of the amplifier (AMP) 2a by switching between the resistor r1 and the resistor r2. This switching operation is performed by a selection signal CTL8 from the CPU 24 in response to the intensity of the ambient light. The output of the amplifier 2a is input to the analog switch AS2 shown by a symbol \odot , as well as to Filter 13. The high-pass H/P filter 13 is provided for cutting the DC components or low frequency components contained in the ambient light.

The analog switch AS2 is switched by a selection signal CTL9 after being inverted by the inverter IV. The output of the amplifier 2a is input to the A/D converter 20 through the analog switch AS2. The analog switch AS3 is switched by the selection signal CTL9 and the signal E is input to the A/D converter 20 through the analog switch AS3.

Figure 10 is a flowchart for explaining the processing of signals in the circuit shown in Fig. 9. This flowchart is the same as shown in Fig. 4 except for the step ②. Accordingly, an explanation is given of the step ②, and explanation of other steps is omitted. In step ②, the CPU resets the number of times C1 of the sampling signal M1 to "0". Next, the CPU performs the processing of the ambient light as explained in detail in Fig. 11, and performs the selection of the gain

of the amplifier 2a and the selection of the reference voltage of the A/D converter 20. Further, the digital signal from the A/D converter 20 is input to the first register 21a in response to the sampling signal CTL4.

Figure 11 is a flowchart for explaining the processing of the ambient light shown in Fig. 10, and Figure 12 is a timing of selection signals. The operation is explained in detail with reference to Figs. 9, 11 and 12.

(1) The CPU 24 turns off the selection signal CTL9 which is input to the analog switches AS2 and AS3. Accordingly, the analog switch AS3 is turned off, but the analog switch AS2 is turned on because the selection signal CTL9 is inverted by the inverter IV. Accordingly, the output of the amplifier 2a is input to the A/D converter 20. During this time, the detection light DL is not emitted from the light emission element 1. Accordingly, the light reception element 2 receives only ambient light from the background. This ambient light is input to the A/D converter 20 through the analog switch AS2 (through the symbol \odot), and converted to the digital signal S3 thereby.

(2) Next, the CPU 24 turns on the selection signal CTL6, and turns off the selection signal CTL7. Based on the selection signals CTL6 and CTL7, the analog switch AS4 is turned on and the analog switch AS5 is turned off. Accordingly, the reference voltage Vref1 having high voltage is applied to the A/D converter 20. At the same time, the CPU 24 turns off the selection signal CTL8 so as to turn off the analog switch AS1. Since the resistor r2 is cut off from a feedback loop of the amplifier the gain of the amplifier 2a is increased because only resistor r1 exists in the feedback loop.

(3) In above situation, the CPU 24 reads the sampling signal S3, which indicates the intensity of the ambient light, from the A/D converter 20. Further, the CPU compares the sampling signal S3 with a threshold value Vth3 of the ambient light.

(4) When the sampling signal S3 exceeds the threshold value Vth3 ("YES"), it is possible to consider that the intensity of the ambient light is larger than the threshold value Vth3. Accordingly, the CPU 24 turns off the selection signal CTL6, and turns on the selection signal CTL7 as shown by dotted line in Fig. 12. Accordingly, the high reference voltage Vref1 is cut off by the analog switch AS4, and the low reference voltage Vref2 is applied to the A/D converter 20 through the analog switch AS5. Further, the CPU 24 turns on the selection signal CTL8 as shown by dotted line in Fig. 12 so as to turn on the analog switch AS1. Since the resistors r1 and r2 are connected in the feedback loop of the amplifier, the gain of the amplifier is decreased by these resistors.

(5) When the sampling signal S3 does not exceed the threshold value Vth3 ("NO"), the state of the

selection signals CTL6 to CTL9 is maintained as shown by the solid lines in Fig. 12. That is, the amplifier 2a is set to a high gain state, and the reference voltage is set to the high reference voltage side. Further, the CPU turns on the selection signal CTL9 when the sampling signal S3 does not exceed the threshold value V_{th3} , or when the amplifier is set to the low gain. When the selection signal CTL9 is turned on, the analog switch AS2 is turned off and the analog switch AS3 is turned on. Accordingly, the sample/hold circuit (S/H) 19 is connected to the A/D converter 20 through the analog switch AS3.

Claims

1. A device for detecting the presence of an article, comprising:
 - light emission means (1) for emitting detection light (DL) for irradiation onto an article; and
 - light reception means (2) for receiving reflected light (RL) from the article; characterised by :
 - an analog-to-digital (A/D) converter (3) for converting the reflected light (RL) to a digital signal (Sd);
 - a first register (4a) for storing the digital signal (Sd) after being sampled using a first sampling signal (M1) having a first period (T1);
 - a second register (4b) for storing the digital signal (Sd) after being sampled using a second sampling signal (M2) having a second period (T2) shorter than the first period (T1); and
 - control means (5) for generating the first and second sampling signals (M1, M2) to be sent to the first and second registers (4a, 4b), reading the digital signal stored in the first and second registers (4a, 4b), calculating a difference between the digital signals in the first register (4a) and second register (4b), comparing an absolute value of the difference with a predetermined threshold value (V_{th}), and detecting the presence of an article when the absolute value is larger than the threshold value (V_{th}).
2. An article detection device as claimed in claim 1, further comprising: an AC-amplifier (9) connected to the light reception means (2) for amplifying the reflected light (RL); a sample/hold means (10) connected between the AC-amplifier (9) and the A/D converter (3) for sampling and holding an alternating signal amplified by the AC-amplifier (9); and modulation means (7) for generating a pulse modulation signal (Sm) to a drive unit (8) which pulse-drives the light emission means (1); wherein the control means (5) further generates

control signals (CTLa, CTLb, CTLc) to be sent to the modulation means (7), the sample/hold means (10), and the A/D converter (3) to control operation of these means (3, 7, 10).

3. An article detection device as claimed in claim 1, wherein the control means (5) comprises a storage means for storing number of sampling times (C1, C2) for the first and second sampling signals (M1, M2), and storing the threshold value (V_{th}) comprised of a first and second threshold values (V_{th1} , V_{th2}).
4. An article detection device as claimed in claim 2, wherein the sample/hold means (10) comprises a maximum sample/hold circuit (17a) for sampling and holding a maximum value of the alternating signal, minimum sample/hold circuit (17b) for sampling and holding a minimum value of the alternating signal, and a differential amplifier (18) for amplifying a difference between outputs of the maximum sample/hold circuit (17a) and the minimum sample/hold circuit (17b).
5. An article detection device as claimed in claim 4, wherein the sample/hold means (10) further comprises a first delay means (22a) for delaying a first sampling signal (CTL1), and a second delay means (22b) for delaying a second sampling signal (CTL2), the first sampling signal (CTL1) being input to the maximum sample/hold circuit (17a), and the second sampling signal (CTL2) being input to the minimum sample/hold circuit (17b).
6. An article detection device as claimed in claim 1, further comprising: difference calculation means (11) having a differential amplifier (20a) for calculating a difference between a level of background reflected light and a lower limitation level, the background reflected light being detected from the background of an article, and the lower limitation level being adjusted in accordance with the intensity of the background reflected light in an adjusting mode; and detection means (12) for detecting a change in the amount of light based on resultant data from the above calculation to eliminate the influence of the background reflected light.
7. An article detection device as claimed in claim 6, wherein the intensity of the background reflection light is determined by a reference reflection surface having a predetermined reflection rate.
8. An article detection device as claimed in claim 6, wherein the detection means comprises a sample/hold circuit (19) for sampling and holding an output of the differential amplifier (18), an adjust-

ing circuit (25) for adjusting a lower limitation level (LL), a first A/D converter (20) for converting an output of the differential amplifier (20a) to a digital value, a second A/D converter (23) for converting the output of the sample/hold circuit (19) to a digital value, and a third A/D converter (26) for converting the output of the adjusting circuit (25) to a digital value.

9. An article detection device as claimed in claim 1, further comprising an adjusting means for adjusting the gain of an amplifier (2a) connected to the light reception element (2), and a reference voltage generation means (27) for generating a first and second reference voltages (Vref1, Vref2) to be supplied to the amplifier (2a), wherein the adjustment of the gain of the amplifier (2a) is performed in such a way that, when ambient light does not exceed a predetermined threshold level, the first reference voltage (Vref1) is selected and the gain is adjusted to a high level state, and when the ambient light exceeds a predetermined threshold level, the second reference voltage (Vref2) is selected and the gain is adjusted to a low level state.

10. An article detection device as claimed in claim 9, wherein the adjusting means comprises a plurality of analog switches (AS1 to AS5), a first analog switch (AS1) being used for switching the gain between the high level state and the low level state, analog switches (AS2, AS3) being used for switching the detection light between the ambient light and the light reflected from an article, and analog switches (AS4, AS5) being used for switching the reference voltage between the first and the second reference voltages (Vref1, Vref2), further, switching of these analog switches being performed by selection signals (CTL6 to CTL9) generated from the control means (24).

11. An article detection device as claimed in claim 1, 3 or 10, wherein the control means (5, 24) comprises a microprocessor (CPU).

12. A method for detecting the presence of an article, comprising the steps of:

emitting detection light (DL) for irradiation onto an article; and

receiving reflected light (RL) from the article; and characterised by the further steps of:

converting the reflection light (RL) to a digital signal (Sd);

storing the digital signal (Sd) in a first register (4a) after being sampled using a first sampling signal (M1) generated by control means (5) and having a first period (T1); and

storing the digital signal (Sd) in a second

register (4b) after being sampled using a second sampling signal (M2) generated by the control means (5) and having a second period (T2) shorter than the first period (T1);

in the control means (5):

reading the digital signal stored in the first and second registers (4a, 4b);

calculating a difference between the digital signals in the first register (4a) and second register (4b);

comparing an absolute value of the difference with a predetermined threshold value (Vth); and

detecting the presence of an article when the absolute value is larger than the threshold value (Vth).

13. A method for detecting an article as claimed in claim 12, wherein the detecting step further comprises the steps of: defining a first and second threshold values (Vth1, Vth2) included in the threshold value (Vth), detecting the presence of an article when the absolute value is larger than the first threshold value (Vth1), and detecting that an article is not present when the absolute value is smaller than the second threshold value (Vth2).

14. A method for detecting an article as claimed in claim 13, wherein the detecting step further comprises the steps of: checking whether or not a number of sampling times (C1) reaches a predetermined number of times (X1) when the absolute value is smaller than the first threshold value (Vth1), and returning to previous sampling steps.

15. A method for detecting an article as claimed in claim 13, wherein the detecting step further comprises the steps of: checking whether or not a number of sampling times (C2) reaches a predetermined number of times (X2) when the absolute value is larger than the second threshold value (Vth2), returning to the previous sampling step of the second sampling signal (M2) when the number of times (C2) of sampling does not reach a predetermined number of times (X2), and detecting that an article is not present when the absolute value is smaller than the second threshold value (Vth2) or when the number of sampling times (C2) reaches a predetermined number of times (X2).

16. A method for detecting an article as claimed in claim 12, further comprising the steps of: setting a first and second reference voltage (Vref1, Vref2), detecting ambient light before detecting the presence of an article; comparing the ambient light with a predetermined threshold value; and adjusting the gain of an amplifier (2a) in accor-

dance with the ambient light so as to switch between a first and second reference voltages.

17. A method for detecting an article as claimed in claim 12, further comprising the steps of: calculating a difference between a level of background reflected light and a lower limitation level in an adjusting mode; and detecting a change in amount of light based on resultant data from the above calculation to eliminate the influence of the background reflected light.

Patentansprüche

1. Vorrichtung zum Detektieren des Vorhandenseins eines Artikels mit:

einer Lichtemissionseinrichtung (1) zum Emittieren von Detektionslicht (DL), um dieses auf einen Artikel aufzustrahlen, und

einer Lichtempfangseinheit (2) zum Empfangen des Reflexionslichtes (RL) von dem Artikel, gekennzeichnet durch:

einen Analog-Digital-(A/D)-Umsetzer (3) zum Umsetzen des Reflexionslichtes (RL) in ein digitales Signal (Sd),

ein erstes Register (4a) zum Speichern des digitalen Signals (Sd), nachdem es gesampelt wurde, wobei ein erstes Samplingsignal (M1) mit einer ersten Periode (T1) verwendet wird,

ein zweites Register (4b) zum Speichern des digitalen Signals (Sd), nachdem es gesampelt wurde, wobei ein zweites Samplingsignal (M2) mit einer zweiten Periode (T2) verwendet wird, die kürzer ist als die erste Periode (T1), und

durch eine Steuereinrichtung (5) zum Erzeugen des ersten und des zweiten Samplingsignals (M1, M2), die zu dem ersten und dem zweiten Register (4a, 4b) zu senden sind, um das in dem ersten und dem zweiten Register (4a, 4b) gespeicherte digitale Signal zu lesen, eine Differenz zwischen den digitalen Signalen in dem ersten Register (4a) und dem zweiten Register (4b) zu berechnen, einen Absolutwert der Differenz mit einem vorbestimmten Schwellenwert (Vth) zu vergleichen und um das Vorhandensein eines Artikels zu detektieren, wenn der Absolutwert größer ist als ein Schwellenwert (Vth).

2. Artikel-Detektionsvorrichtung nach Anspruch 1, die ferner enthält: einen Wechselstromverstärker (9), der an die Lichtempfangseinrichtung (2) angeschlossen ist, um das Reflexionslicht (RL) zu verstärken, eine Sample-/Halteeinrichtung (10), die zwischen den Wechselstromverstärker (9) und den A/D-Umsetzer (3) geschaltet ist, um ein alternierendes Signal zu sampeln und zu speichern, welches durch den Wechselstromverstär-

ker (9) verstärkt wurde, und eine Modulationseinrichtung (7) zum Erzeugen eines Impulsmodulationssignals (Sm), für eine Treibereinheit (8), die die Lichtemissionseinrichtung (1) impulsmäßig treibt, wobei die Steuereinrichtung (5) Steuersignale (CTLa, CTLe, CTLc) erzeugt, die zu der Modulationseinrichtung (7), der Sample-/Halteeinrichtung (10) und dem A/D-Umsetzer (3) zu senden sind, um den Betrieb dieser Einrichtungen (3, 7, 10) zu steuern.

3. Artikel-Detektionsvorrichtung nach Anspruch 1, bei der die Steuereinrichtung (5) eine Speichereinrichtung enthält, um die Zahl von Malen von Samplingvorgängen (C1, C2) für das erste und das zweite Samplingsignal (M1, M2) zu speichern, und um den Schwellenwert (Vth) zu speichern, der aus einem ersten und einem zweiten Schwellenwert (Vth1, Vth2) besteht.

4. Artikel-Detektionsvorrichtung nach Anspruch 2, bei der die Sample-/Halteeinrichtung (10) eine Maximum-Sample-/Halteschaltung (17a) umfaßt, um einen Maximalwert des alternierenden Signals zu sampeln und zu speichern, eine Minimum-Sample-/Halteschaltung (17b) umfaßt, um einen Minimalwert des alternierenden Signals zu sampeln und zu speichern, und einen Differenzverstärker (18) umfaßt, um eine Differenz zwischen den Ausgangsgrößen der Maximum-Sample-/Halteschaltung (17a) und der Minimum-Sample-/Halteschaltung (17b) zu verstärken.

5. Artikel-Detektionsvorrichtung nach Anspruch 4, bei der die Sample-/Halteeinrichtung (10) ferner eine erste Verzögerungseinrichtung (22a) zum Verzögern eines ersten Samplingsignals (CTL1) enthält, und eine zweite Verzögerungseinrichtung (22b) zum Verzögern eines zweiten Samplingsignals (CTL2) umfaßt, wobei das erste Samplingsignal (CTL1) in die Maximum-Sample-/Halteschaltung (17a) eingegeben wird und das zweite Samplingsignal (CTL2) in die Minimum-Sample-/Halteschaltung (17b) eingegeben wird.

6. Artikel-Detektionsvorrichtung nach Anspruch 1, die ferner enthält: eine Differenzberechnungseinrichtung (11) mit einem Differenzverstärker (20a) zum Berechnen einer Differenz zwischen einem Wert des vom Hintergrund reflektierten Lichtes und einem unteren Grenzwert, wobei das vom Hintergrund reflektierte Licht von dem Hintergrund eines Artikels detektiert wird und wobei der untere Grenzwert entsprechend der Intensität des vom Hintergrund reflektierten Lichts in einer Einstellbetriebsart eingestellt wird, und eine Detektionseinrichtung (12) zum Detektieren ei-

ner Änderung in der Lichtmenge auf der Grundlage von sich aus der obigen Berechnung ergebenden Resultatdaten, um den Einfluß des vom Hintergrund reflektierten Lichtes zu beseitigen.

7. Artikel-Detektionsvorrichtung nach Anspruch 6, bei der die Intensität des vom Hintergrund reflektierten Lichtes mit Hilfe einer Bezugsreflexionsoberfläche mit einem vorbestimmten Reflexionsgrad bestimmt wird.

8. Artikel-Detektionsvorrichtung nach Anspruch 6, bei der die Detektionseinrichtung eine Sample-/Halteschaltung (19) umfaßt, um eine Ausgangsgröße des Differenzverstärkers (18) zu sampeln und zu speichern, eine Einstellschaltung (25) umfaßt, um einen unteren Grenzwert (LL) einzustellen, einen ersten A/D-Umsetzer (20) zum Umsetzen einer Ausgangsgröße des Differenzverstärkers (20a) in einen digitalen Wert, einen zweiten A/D-Umsetzer (23) zum Umsetzen der Ausgangsgröße der Sample-/Halteschaltung (19) in einen digitalen Wert, und einen dritten A/D-Umsetzer (26) zum Umsetzen der Ausgangsgröße der Einstellschaltung (25) in einen digitalen Wert.

9. Artikel-Detektionsvorrichtung nach Anspruch 1, die ferner enthält eine Einstelleinrichtung zum Einstellen der Verstärkung eines Verstärkers (2a), der an das Lichtempfangselement (2) angeschlossen ist, und eine eine Bezugsspannung erzeugende Einrichtung (27) zum Erzeugen einer ersten und einer zweiten Bezugsspannung (Vref1, Vref2), die an den Verstärker (2a) anzulegen sind, wobei die Einstellung der Verstärkung des Verstärkers (2a) auf solche Weise durchgeführt wird, daß dann, wenn das Umgebungslicht einen vorbestimmten Schwellenwert nicht überschreitet, die erste Bezugsspannung (Vref1) ausgewählt wird und die Verstärkung auf einen Zustand gemäß einem hohen Wert eingestellt wird, und wenn das Umgebungslicht einen vorbestimmten Schwellenwert überschreitet, die zweite Bezugsspannung (Vref2) ausgewählt wird und die Verstärkung auf einen Zustand gemäß einem niedrigen Wert eingestellt wird.

10. Artikel-Detektionsvorrichtung nach Anspruch 9, bei der die Einstelleinrichtung eine Vielzahl von Analogschaltern (AS1 bis AS5) umfaßt, wobei ein erster Analogschalter (AS1) dazu verwendet wird, um die Verstärkung zwischen dem Zustand gemäß dem hohen Wert und dem Zustand gemäß dem niedrigen Wert umzuschalten, die Analogschalter (AS2, AS3) dazu verwendet werden, um das Detektionslicht zwischen dem Umgebungslicht und dem vom Artikel reflektierten Licht umzuschalten, und Analogschalter (AS4,

AS5) dazu verwendet werden, um die Bezugsspannung zwischen der ersten und der zweiten Bezugsspannung (Vref1, Vref2) umzuschalten, wobei ferner das Umschalten dieser Analogschalter durch Wählsignale (CTL6 bis CTL9) durchgeführt wird, die durch die Steuereinrichtung (24) erzeugt werden.

11. Artikel-Detektionsvorrichtung nach Anspruch 1, 3 oder 10, bei der die Steuereinrichtung (5, 24) einen Mikroprozessor (CPU) umfaßt.

12. Verfahren zum Detektieren des Vorhandenseins eines Artikels, mit den folgenden Schritte:

Emittieren von Detektionslicht (DL), um dieses auf einen Artikel aufzustrahlen, und Empfangen von Reflexionslicht (RL) von dem Artikel, gekennzeichnet durch die folgenden weiteren Schritte:

Umsetzen des Reflexionslichtes (RL) in ein digitales Signal (Sd),

Speichern des digitalen Signals (Sd) in einem ersten Register (4a), nachdem es gesampelt wurde, wobei ein erstes Samplingsignal (M1) verwendet wird, welches durch die Steuereinrichtung (5) erzeugt wurde und eine erste Periode (T1) besitzt, und

Speichern des digitalen Signals (Sd) in einem zweiten Register (4b), nachdem es gesampelt wurde, wobei ein zweites Samplingsignal (M2) verwendet wird, welches von der Steuereinrichtung (5) erzeugt wurde und eine zweite Periode (T2) besitzt, die kürzer ist als die erste Periode (T1),

wobei in der Steuereinrichtung (5) folgende Schritte durchgeführt werden:

Lesen des digitalen Signals, welches in dem ersten und dem zweiten Register (4a, 4b) gespeichert ist,

Berechnen einer Differenz zwischen den digitalen Signalen in dem ersten Register (4a) und dem zweiten Register (4b),

Vergleichen eines Absolutwertes der Differenz mit einem vorbestimmten Schwellenwert (Vth) und

Detektieren des Vorhandenseins eines Artikels, wenn der Absolutwert größer ist als der Schwellenwert (Vth).

13. Verfahren zum Detektieren eines Artikels nach Anspruch 12, wonach der Detektionsschritt ferner die folgenden Schritte umfaßt: Definieren eines ersten und zweiten Schwellenwertes (Vth1, Vth2), die in dem Schwellenwert (Vth) enthalten sind, Detektieren des Vorhandenseins eines Artikels, wenn der Absolutwert größer ist als der erste Schwellenwert (Vth1) und Detektieren, daß ein Artikel nicht vorhanden ist, wenn der Absolutwert kleiner ist als der zweite Schwellenwert

(Vth2).

14. Verfahren zum Detektieren eines Artikels nach Anspruch 13, wonach der Detektionsschritt ferner die folgenden Schritte umfaßt: Prüfen, ob eine Zahl von Malen (C1) von Samplingvorgängen eine vorbestimmte Zahl von Malen (X1) erreicht oder nicht, wenn der Absolutwert kleiner ist als der erste Schwellenwert (Vth1), und Rückkehren zu den früheren Samplingschritten. 5
15. Verfahren zum Detektieren eines Artikels nach Anspruch 13, wonach der Detektionsschritt ferner die Schritte umfaßt: Prüfen, ob eine Anzahl von Malen (C2) von Samplingvorgängen eine vorbestimmte Zahl von Malen von Samplingvorgängen (X2) erreicht oder nicht, wenn der Absolutwert größer ist als der zweite Schwellenwert (Vth2), Rückkehren zu dem früheren Samplingschritt des zweiten Samplingsignals (M2), wenn die Zahl von Malen (C2) von Samplingvorgängen eine vorbestimmte Zahl von Malen (X2) nicht erreicht, und Detektieren, daß ein Artikel nicht vorhanden ist, wenn der Absolutwert kleiner ist als der zweite Schwellenwert (Vth2) oder wenn die Zahl von Malen (C2) von Samplingvorgängen eine vorbestimmte Zahl von Malen (X2) erreicht. 10 15 20 25
16. Verfahren zum Detektieren eines Artikels nach Anspruch 12, welches ferner die folgenden Schritte umfaßt: Setzen einer ersten und einer zweiten Bezugsspannung (Vref1, Vref2), Detektieren des Umgebungslichtes vor dem Detektieren des Vorhandenseins eines Artikels, Vergleichen des Umgebungslichtes mit einem vorbestimmten Schwellenwert und Einstellen der Verstärkung eines Verstärkers (2a) in Einklang mit dem Umgebungslicht, um zwischen einer ersten und der zweiten Bezugsspannung umzuschalten. 30 35 40
17. Verfahren zum Detektieren eines Artikels nach Anspruch 12, welches ferner die folgenden Schritte umfaßt: Berechnen einer Differenz zwischen einem Wert des vom Hintergrund reflektierten Lichtes und einem unteren Grenzwert in einer Einstellbetriebsart und Detektieren einer Änderung des Umgebungslichtes auf der Grundlage der aus der obigen Berechnung erhaltenen Resultatdaten, um den Einfluß des vom Hintergrund reflektierten Lichtes zu beseitigen. 45 50

Revendications

1. Dispositif pour détecter la présence d'un article comprenant : 55
 - un dispositif d'émission de lumière (1) pour émettre de la lumière de détection (DL) pour

une irradiation sur un article ; et
 un dispositif de réception de lumière (2) pour recevoir de la lumière réfléchie (RL) par l'article ;
 caractérisé par :
 un convertisseur analogique numérique (A/D) (3) pour convertir la lumière réfléchie (RL) en un signal numérique (Sd) ;
 un premier registre (4a) pour stocker le signal numérique (Sd) après qu'il ait été échantillonné en utilisant un premier signal d'échantillonnage (M1) ayant une première période (T1) ;
 un second registre (4b) pour stocker le signal numérique (Sd) après qu'il ait été échantillonné en utilisant un second signal d'échantillonnage (M2) ayant une seconde période (T2) plus courte que la première période (T1) ; et
 un dispositif de commande (5) pour générer les premier et second signaux d'échantillonnage (M1, M2) à envoyer aux premier et second registres (4a, 4b), pour lire le signal numérique stocké dans les premier second registres (4a, 4b), pour calculer une différence entre les signaux numériques dans le premier registre (4a) et le second registre (4b), pour comparer une valeur absolue de la différence avec une valeur de seuil prédéterminée (Vth), et pour détecter la présence d'un article lorsque la valeur absolue est plus grande que la valeur de seuil (Vth).

2. Dispositif de détection d'article selon la revendication 1, comprenant de plus : un amplificateur à courant alternatif (9) relié au dispositif de réception de lumière (2) pour amplifier la lumière réfléchie (RL) ; un dispositif d'échantillonnage et de maintien (10) relié entre l'amplificateur à courant alternatif (9) et le convertisseur A/D (3) pour échantillonner et maintenir un signal alternatif amplifié par l'amplificateur à courant alternatif (9) ; et un dispositif de modulation (7) pour générer un signal de modulation d'impulsion (Sm) pour une unité de commande (8) qui commande par impulsion le dispositif d'émission de lumière (1) ; dans lequel le dispositif de commande (5) génère en outre des signaux de commande (CTLa, CTLe, CTLc) à envoyer au dispositif de modulation (7), au dispositif d'échantillonnage et de maintien (10), et au convertisseur A/D (3) pour commander le fonctionnement de ces dispositifs (3, 7, 10).

3. Dispositif de détection d'article selon la revendication 1, dans lequel le dispositif de commande (5) comprend un dispositif de stockage pour stocker un nombre de fois d'échantillonnage (C1, C2) pour les premier et second signaux d'échantillonnage (M1, M2), et pour stocker la valeur de seuil (Vth) composée des première et seconde

valeurs de seuil (V_{th1} , V_{th2}).

4. Dispositif de détection d'article selon la revendication 2, dans lequel le dispositif d'échantillonnage et de maintien (10) comprend un circuit d'échantillonnage et de maintien maximum (17a) pour échantillonner et maintenir une valeur maximum du signal alternatif, un circuit d'échantillonnage et de maintien minimum (17b) pour échantillonner et maintenir une valeur minimum du signal alternatif et un amplificateur différentiel (18) pour amplifier une différence entre des sorties du circuit d'échantillonnage et de maintien maximum (17a) et du circuit d'échantillonnage et de maintien minimum (17b).
5. Dispositif de détection d'article selon la revendication 4, dans lequel le dispositif d'échantillonnage et de maintien (10) comprend en outre un premier dispositif à retard (22a) pour retarder un premier signal d'échantillonnage (CTL1) et un second dispositif à retard (22b) pour retarder un second signal d'échantillonnage (CTL2), le premier signal d'échantillonnage (CTL1) étant appliqué au circuit d'échantillonnage et de maintien maximum (17a), et le second signal d'échantillonnage (CTL2) étant appliqué au circuit d'échantillonnage et de maintien minimum (17b).
6. Dispositif de détection d'article selon la revendication 1, comprenant en outre : un dispositif de calcul de différence (11) ayant un amplificateur différentiel (20a) pour calculer une différence entre un niveau de lumière réfléchie d'arrière plan et un niveau de limitation inférieur, la lumière réfléchie d'arrière plan étant détectée de l'arrière plan d'un article, et le niveau de limitation inférieur étant réglé en fonction de l'intensité de la lumière réfléchie d'arrière plan en mode de réglage ; et un dispositif de détection (12) pour détecter une variation de quantité de lumière en fonction des données résultant du calcul ci-dessus pour éliminer l'influence de la lumière réfléchie ambiante.
7. Dispositif de détection d'article selon la revendication 6, dans lequel l'intensité de la lumière réfléchie d'arrière plan est déterminée par une surface de réflexion de référence ayant un taux de réflexion prédéterminé.
8. Dispositif de détection d'article selon la revendication 6, dans lequel le dispositif de détection comprend un circuit d'échantillonnage et de maintien (19) pour échantillonner et maintenir une sortie de l'amplificateur différentiel (18), un circuit de réglage (25) pour régler un niveau de limitation inférieur (LL), un premier convertisseur

A/D (20) pour convertir une sortie de l'amplificateur différentiel (20a) en une valeur numérique, un second convertisseur A/D (23) pour convertir la sortie du circuit d'échantillonnage et de maintien (19) en une valeur numérique, et un troisième convertisseur A/D (26) pour convertir la sortie du circuit de réglage (25) en une valeur numérique.

9. Dispositif de détection d'article selon la revendication 1, comprenant en outre un dispositif de réglage pour régler le gain d'un amplificateur (2a) relié à l'élément de réception de lumière (2) et un dispositif de génération de tension de référence (27) pour générer des première et seconde tensions de référence (V_{ref1} , V_{ref2}) à appliquer à l'amplificateur (2a), dans lequel le réglage du gain de l'amplificateur (2a) est réalisé de telle sorte que, lorsque la lumière ambiante ne dépasse pas un niveau de seuil prédéterminé, la première tension de référence (V_{ref1}) est sélectionnée et le gain est réglé à un état de niveau haut, et lorsque la lumière ambiante dépasse un niveau de seuil prédéterminé, la seconde tension de référence (V_{ref2}) est sélectionnée et le gain est réglé à un état de niveau bas.
10. Dispositif de détection d'article selon la revendication 9, dans lequel le dispositif de réglage comprend une pluralité de commutateurs analogiques (AS1 à AS5), un premier commutateur analogique (AS1) étant utilisé pour commuter le gain entre l'état de niveau haut et l'état de niveau bas, des commutateurs analogiques (AS2, AS3) étant utilisés pour commuter entre la lumière de détection entre la lumière ambiante et la lumière réfléchie par un article et des commutateurs analogiques (AS4, AS5) étant utilisés pour commuter la tension de référence entre les première et seconde tensions de référence (V_{ref1} , V_{ref2}), en outre la commutation de ces commutateurs analogiques étant réalisée par des signaux de sélection (CTL6 à CTL9) générés par le dispositif de commande (24).
11. Dispositif de détection d'article selon la revendication 1, 3, ou 10, dans lequel le dispositif de commande (5, 24) comprend un microprocesseur (CPU).
12. Procédé de détection de la présence d'un article comprenant les étapes de :
émission de lumière de détection (DL) pour une irradiation sur un article ; et
réception de la lumière réfléchie (RL) par l'article ; et caractérisé par les autres étapes de :
conversion de la lumière réfléchie (RL) en un signal numérique (Sd) ;
stockage du signal numérique (Sd) dans

un premier registre (4a) après qu'il ait été échantillonné en utilisant un premier signal d'échantillonnage (M1) généré par un dispositif de commande (5) et ayant une première période (T1) ; et

stockage du signal numérique (Sd) dans un second registre (4b) après qu'il ait été échantillonné en utilisant un second signal d'échantillonnage (M2) généré par un dispositif de commande (5) et ayant une seconde période (T2) plus courte que la première période (T1) ;

Dans le dispositif de commande (5):

lecture du signal numérique stocké dans les premier et second registres (4a, 4b) ;

calcul d'une différence entre les signaux numériques dans le premier registre (4a) et le second registre (4b) ;

comparaison d'une valeur absolue de la différence avec une valeur de seuil prédéterminée (Vth); et

détection de la présence d'un article lorsque la valeur absolue est plus grande que la valeur de seuil (Vth).

13. Procédé pour détecter un article selon la revendication 12, dans lequel l'étape de détection comprend en outre les étapes de : définition des première et seconde valeurs de seuil (Vth1, Vth2) comprise dans la valeur de seuil (Vth), détection de la présence d'un article lorsque la valeur absolue est plus grande que la première valeur de seuil (Vth1), et détection qu'un article n'est pas présent lorsque la valeur absolue est plus petite que la seconde valeur de seuil (Vth2).

14. Procédé pour détecter un article selon la revendication 13, dans lequel les étapes de détection comprennent en outre les étapes de : contrôle si oui ou non un nombre de fois d'échantillonnage (C1) atteint un nombre prédéterminé de fois (X1) lorsque la valeur absolue est plus petite que la première valeur de seuil (Vth1), et retour aux étapes d'échantillonnage antérieure.

15. Procédé pour détecter un article selon la revendication 13, dans lequel l'étape de détection comprend en outre les étapes de : contrôle si oui ou non un nombre de fois d'échantillonnage (C2) atteint un nombre prédéterminé de fois (X2) lorsque la valeur absolue est supérieure à la seconde valeur de seuil (Vth2), retour à l'étape d'échantillonnage précédente du second signal d'échantillonnage (M2) lorsque le nombre de fois (C2) d'échantillonnage n'atteint pas un nombre de fois prédéterminé (X2), et détection qu'un article n'est pas présent lorsque la valeur absolue est plus petite que la seconde valeur de seuil (Vth2) ou lorsque le nombre de fois d'échantillonnage (C2) at-

teint un nombre de fois prédéterminé (X2).

16. Procédé pour détecter un article selon la revendication 12, comprenant en outre les étapes de : réglage d'une première et seconde tension de référence (Vref1, Vref2), détection de la lumière ambiante avant de détecter la présence d'un article ; comparaison de la lumière ambiante avec une valeur de seuil prédéterminée ; et réglage du gain d'un amplificateur (2a) selon la lumière ambiante afin de commuter entre des première et seconde tensions de référence.
17. Procédé pour détecter un article selon la revendication 12, comprenant en outre les étapes de : calcul d'une différence entre un niveau de lumière réfléchie d'arrière plan et un niveau de limitation inférieur dans un mode de réglage ; et détection d'une variation de quantité de lumière sur la base des données résultant du calcul ci-dessus pour éliminer l'influence de la lumière réfléchie d'arrière-plan.
